VERIFICATION OF FLAG ALGEBRAS GENERATED RESULTS

Full verification

The verification programs are written in Python 3. The full verification, which takes around 85 hours in a modern personal computer, can be performed by executing the `full-verify` program inside a folder containing all six certificates:

```
$ python3 full-verify.py
```

The program calls the `validator` and `verifier` programs on each certificate. The calls are made in the following way:

```
$ python3 validator.py prop_3_1_c5k4.pickle
$ python3 verifier.py prop_3_1_c5k4.pickle
```

Validate objectives and assumptions

The `validator` program loads a certificate as a Python pickle file and verifies that that the objective function and positivity assumptions of its corresponding proposition are correctly translated into the certificate. Its usage message is the following.

```
usage: validator.py [-h] {prop_3_1_c5k4.pickle,prop_3_1_c7.pickle,
                         prop_3_2_c5k4.pickle,prop_3_2_c7.pickle,
                         prop_3_3_c5k4.pickle,prop_3_3_c7.pickle}

Validates that the objectives and assumptions of a given certificate correspond
to those in the corresponding proposition.

positional arguments:
  {prop_3_1_c5k4.pickle,prop_3_1_c7.pickle,prop_3_2_c5k4.pickle,
   prop_3_2_c7.pickle,prop_3_3_c5k4.pickle,prop_3_3_c7.pickle}
                        path of the pickle file

options:
  -h, --help            show this help message and exit

examples:
  $ python validator.py prop_3_1_c5k4.pickle
```

The objective functions and positivity assumptions for each propositions can be found in the following locations.

- Proposition 3.1: Lines 179–186.
- Proposition 3.2: Lines 189–250.

- Proposition 3.3: Lines 253–374.

Verify the certificates

The verifier program loads a certificate as a Python pickle file, interactively asks for a pair of indices, and then verifies the constraints corresponding to the user-specified range. Its usage message is the following.

```
usage: verifier.py [-h] [-p] [-v {1,2,3}] certificate

A simple flag algebras certificate verifier.

positional arguments:
  certificate           path of the pickle file

options:
  -h, --help            show this help message and exit
  -p, --partial         partial verification
  -v {1,2,3}, --verbose {1,2,3}
                        verbosity level
                        default: 1

examples:
  $ python verify.py c5k4-bad-missing.pickle

  $ python verify.py c5k4-bad-missing.pickle -p
  Enter two integers in the range [1,28080] (e.g., '1 14040'): 1 10

  $ python verifier.py c5k4-bad-missing.pickle -p -v 2
  Enter two integers in the range [1,28080] (e.g., '1 14040'): 5 5
```

Verifier specification

We work in the theory of 3-uniform hypergraphs, where every vertex is either red or blue. For a type τ and integers $m' \leq m$ such that $2m' - |\tau| \leq m$, we make the following definitions.

- $\mathcal{F}^\tau_m$ is the set of all flags with type τ (τ-flags) with m vertices in the theory. We also let $\mathcal{F}_m = \mathcal{F}^\varnothing_m$.
- $\mathbb{R}F^\tau_m$ is the set of formal real linear combinations of flags from $\mathcal{F}^\tau_m$.
- For τ-flags $H_1, H_2 \in \mathcal{F}^\tau_{m'}$, let $H_1 \times H_2 = \sum_{G \in \mathcal{F}^\tau_{2m'-|\tau|}} d\left(H_1, H_2, G\right) G$.
- $\mathcal{F}^\tau_{m'} \otimes \mathcal{F}^\tau_{m'} \in \left(\mathbb{R}\mathcal{F}^\tau_{2m'-|\tau|}\right)^{\mathcal{F}^\tau_{m'} \times \mathcal{F}^\tau_{m'}}$ is a symmetric matrix with lines indexed by $\mathcal{F}^\tau_{m'}$ whose (H_1, H_2)-entry is $H_1 \times H_2$.
- $\left[\!\left[\mathcal{F}^\tau_{m'} \otimes \mathcal{F}^\tau_{m'}\right]\!\right]_\tau \in \left(\mathbb{R}\mathcal{F}_{2m'-|\tau|}\right)^{\mathcal{F}^\tau_{m'} \times \mathcal{F}^\tau_{m'}}$ is the matrix obtained from $\mathcal{F}^\tau_{m'} \otimes \mathcal{F}^\tau_{m'}$ by applying entry-wise the averaging operator. Each entry is a linear combination of flags from $\mathcal{F}_{2m'-|\tau|}$.
- For a flag $F \in \mathcal{F}_m$, we let $M^{\tau,m}_F \in \mathbb{R}^{\mathcal{F}^\tau_{m'} \times \mathcal{F}^\tau_{m'}}$ be the real symmetric matrix obtained from $\left[\!\left[\mathcal{F}^\tau_{m'} \otimes \mathcal{F}^\tau_{m'}\right]\!\right]_\tau$ by applying entry-wise the $p(\cdot, F)$ density operator.

We now fix:

(i) $T \in \mathbb{R}\mathcal{F}_m$, a target linear combination of flags,

(*ii*) $\lambda \in \mathbb{R}$, a bound,
(*iii*) $(\tau_1, n_1), \ldots, (\tau_k, n_k)$, a sequence of types and sizes,
(*iv*) $X^{\tau_1}, \ldots, X^{\tau_k}$, a sequence of square matrices.
(*v*) $e_1, \ldots, e_p$, a sequence of coefficients $e_i \in \mathbb{R}$.
(*vi*) $f^{(1)}, \ldots, f^{(p)}$, a sequence of elements $f^{(i)} \in \mathbb{R}\mathcal{F}_m$.

Then, we need to verify that:

$$\text{the matrices } X^{\tau_1}, \ldots, X^{\tau_k} \text{ are positive semidefinite,} \tag{1}$$

and for all $F \in \mathcal{F}_m$ and coefficients $c_F \geq 0$,

$$\lambda - p(T, F) = \sum_{i \in [k]} \langle M_F^{\tau_i, m_i}, X^{\tau_i} \rangle + \sum_{i \in [p]} e_i p(f^{(i)}, F) + c_F. \tag{2}$$

The verification of (1) is done by attempting to decompose a matrix $M = LDL^{\mathrm{T}}$, where L is a lower triangular matrix with 1's on the diagonal, and D is a diagonal matrix. If the decomposition reconstructs M, and all diagonal entries of D are non-negative, then we conclude that M is positive semidefinite.

Given that the verification of (2) may be computationally intensive, the program verifies a user-specified subset of $\mathcal{F}_m$. More precisely, given an ordering of the set

$$\mathcal{F}_m = \{F_1, F_2, \ldots, F_\ell\}, \tag{3}$$

specified by the certificate, and a user-specified pair of indices i, j, the program verifies (2) for F_p, with $i \leq p \leq j$. By default, this range is $[\ell]$, i.e., the program completely verifies (2). If the verification fails at some point, the program stops and reports the failure.

A certificate is a Python pickle file containing a serialized dictionary with string keys. All numerical values in the certificate are `Fraction` objects. The structure of the dictionary is as follows:

- `"target"`: The target element in (*i*), given as a list $(t_i)_{i \in [\ell]}$, where $T = t_1 F_1 + \cdots t_\ell F_\ell$.
- `"result"`: The value in (*ii*).
- `"X matrices"`: List $(X^{\tau_i})_{i \in [k]}$ of the matrices in (*iv*). Each matrix is given as a list representing a flattened matrix.
- `"e vector"`: List $(e_i)_{i \in [p]}$ of coefficients in (*v*).
- `"positives"`: List $(f^{(i)})_{i \in [p]}$ of positivity constraints in (*vi*). Each element $f^{(i)}$ is given as a list $(f_j^{(i)})_{j \in [\ell]}$, where $f^{(i)} = f_1^{(i)} F_1 + \cdots + f_\ell^{(i)} F_\ell$.
- `"base flags"`: List $(F_i)_{i \in [\ell]}$ of the flags in (3). Each flag is given as a tuple with the following values:
  - Integer `k`, the number of vertices in the flag. The vertices of the flag are the integers $0, 1, \ldots, k-1$.
  - Tuple `t` of integers, the typed vertices of the flag in the labeling order. So, `t[0]` is the vertex assigned to label 0, and so on.
  - Tuple or ordered pairs `(r, l)` identifying relations. The value `r` is the name of the relation, one of the strings `edges`, `C0` or `C1`. The value `l` is a tuple identifying the elements of the relation. Each element of the relation is a tuple containing the vertices in the relation. For example, this is a valid tuple of ordered pairs: `( ("edges", ((0, 1, 2)) ), ("C0", ((0), (1)) ), ("C1",(2)) )`. The vertices in the relation `C1` are the blue vertices. Every other vertex (i.e., those in `C0`) is red. The relations `C0` and `C1` are either both present, or both missing, in which case all the vertices are red.

- `"typed flags"`: Dictionary, where keys are pairs `(m,t)`, where `m` is an integer, and `t` is a type τ_i from *(iii)* in the flag format specified in the previous item. For a key (m_i, τ_i), its corresponding value is a list of the elements in $\mathcal{F}_{m_i}^{\tau_i}$ in flag format.
- `"slack vector"`: List $(c_{F_i})_{i\in[\ell]}$ of the non-negative slack coefficients in (2).
